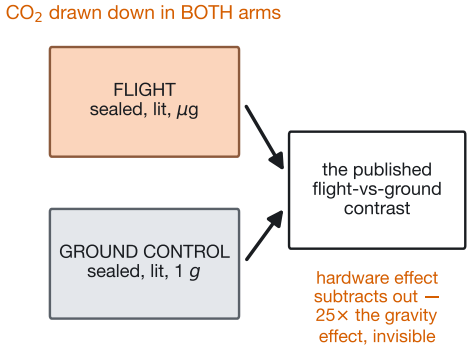
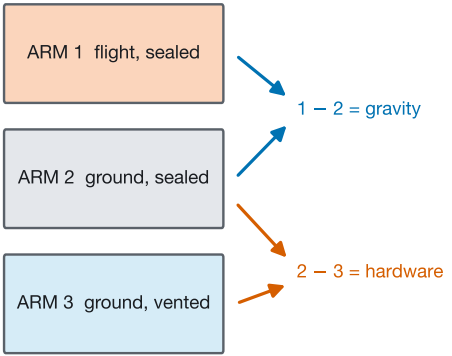
Designing the experiment that could tell hardware from gravity

a What the standard contrast cannot see



What survives is a persistent ~5–9 % assimilation penalty, and downstream of it a carbon-starvation signature — which is what the omics show.

b The design that separates them



Two arms confound the two effects. Three separate them — and the third arm needs no flight.

c The gap this ran into

0 of 66

OSDR plant studies with a metabolome

6 of 567

OSDR studies that are metabolite profiling, all mouse, human, rat or microbial

0

in-canister CO_2 logs, any BRIC-class flight

A ~20-compound targeted panel on archived material would be the first plant spaceflight metabolome.
